Vectorization, GPUs, and CUDA

Goals of Today's Lecture

- Benefits of vectorization
- Understanding GPU architectures
- Crash course in CUDA

$$\hat{\mathbf{y}} = \mathbf{W}\mathbf{x} + \mathbf{b}$$

$$\hat{\mathbf{y}} = \mathbf{W}\mathbf{x} + \mathbf{b}$$

Three implementations

Explicit computation

$$\hat{y}_{ij} = \sum_{k} w_{ik} x_{kj} + b_i$$

Note:

- i ranges over output variables
- j ranges over (training) instances
- k ranges over predictors

$$\hat{\mathbf{y}} = \mathbf{W}\mathbf{x} + \mathbf{b}$$

Three implementations

Explicit computation Single instance

$$\hat{y}_{ij} = \sum_{k} w_{ik} x_{kj} + b_i \qquad \qquad \hat{\mathbf{y}}_j = \mathbf{W} \mathbf{x}_j + \mathbf{b}$$

Note:

- i ranges over output variables
- j ranges over (training) instances
- k ranges over predictors

$$\hat{\mathbf{y}} = \mathbf{W}\mathbf{x} + \mathbf{b}$$

Three implementations

Explicit computation Single instance Batch

$$\hat{y}_{ij} = \sum_{k} w_{ik} x_{kj} + b_i$$
 $\hat{\mathbf{y}}_j = \mathbf{W} \mathbf{x}_j + \mathbf{b}$ $\hat{\mathbf{Y}} = \mathbf{W} \mathbf{X} +_{\text{colwise}} \mathbf{b}$

Note:

- i ranges over output variables
- j ranges over (training) instances
- k ranges over predictors

Linear Regression Speed

Four different algorithms

- Explicit computation CPU (C++ implementation)
- Per-instance vectorization CPU (Eigen C++ library)
- Per-batch vectorization CPU (Eigen C++ library)
- Per-batch vectorization GPU (CUBLAS library)

Six different problem sizes

- *i*={256, 512, ..., 16384} (outputs), *k*=8192 (covariates), *j*=128 (batch size)
- CPU: Intel(R) Xeon(R) CPU E5-2630 v3 @ 2.40GHz
- GPU: NVIDIA Tesla K40

Implementations

Explicit computation (CPU)

```
for (int i = 0; i < hsize; ++i)
  for (int j = 0; j < msize; ++j) {
    Y3(i,j) = b(i);
    for (int k = 0; k < xsize; ++k)
        Y3(i,j) += W(i,k) * X(k,j);
}</pre>
```

Implementations

Explicit computation (CPU)

```
for (int i = 0; i < hsize; ++i)
  for (int j = 0; j < msize; ++j) {
    Y3(i,j) = b(i);
    for (int k = 0; k < xsize; ++k)
        Y3(i,j) += W(i,k) * X(k,j);
}</pre>
```

Per-instance vectorization (CPU)

```
for (int m = 0; m < msize; ++m) {
   Y2.col(m) = W * X.col(m) + b;
}</pre>
```

Implementations

Explicit computation (CPU)

```
for (int i = 0; i < hsize; ++i)
  for (int j = 0; j < msize; ++j) {
    Y3(i,j) = b(i);
    for (int k = 0; k < xsize; ++k)
        Y3(i,j) += W(i,k) * X(k,j);
}</pre>
```

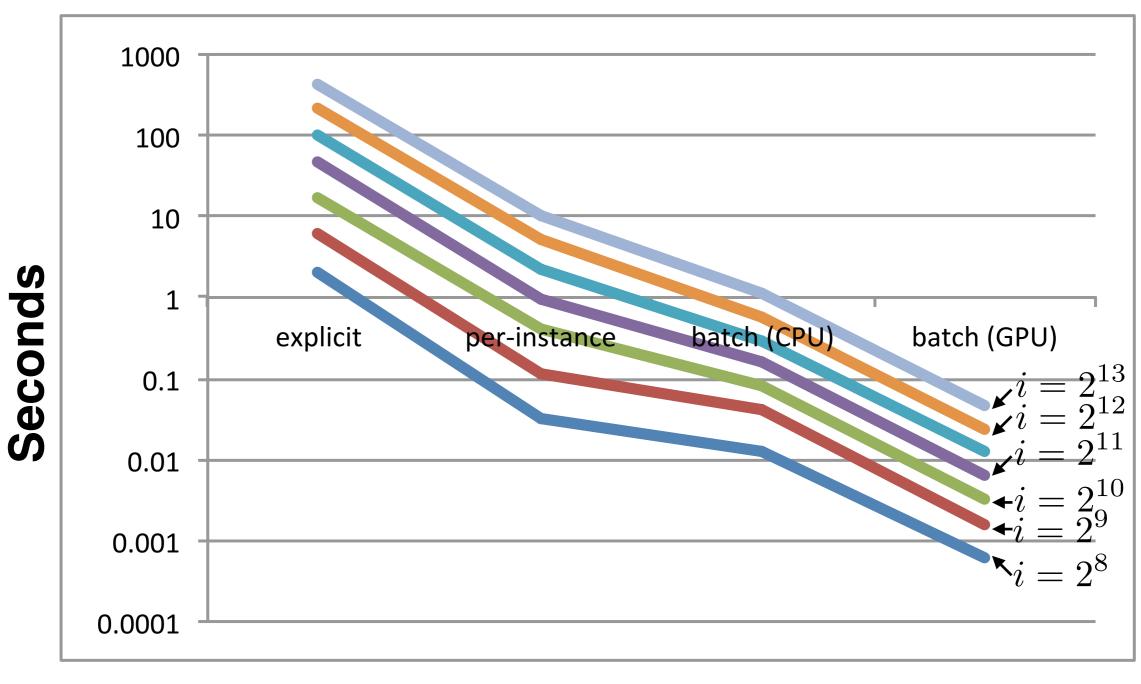

Per-instance vectorization (CPU)

```
for (int m = 0; m < msize; ++m) {
   Y2.col(m) = W * X.col(m) + b;
}</pre>
```

Per-batch vectorization (CPU)

```
Y1 = (W * X).colwise() + b;
```

Linear Regression Speed

Algorithm

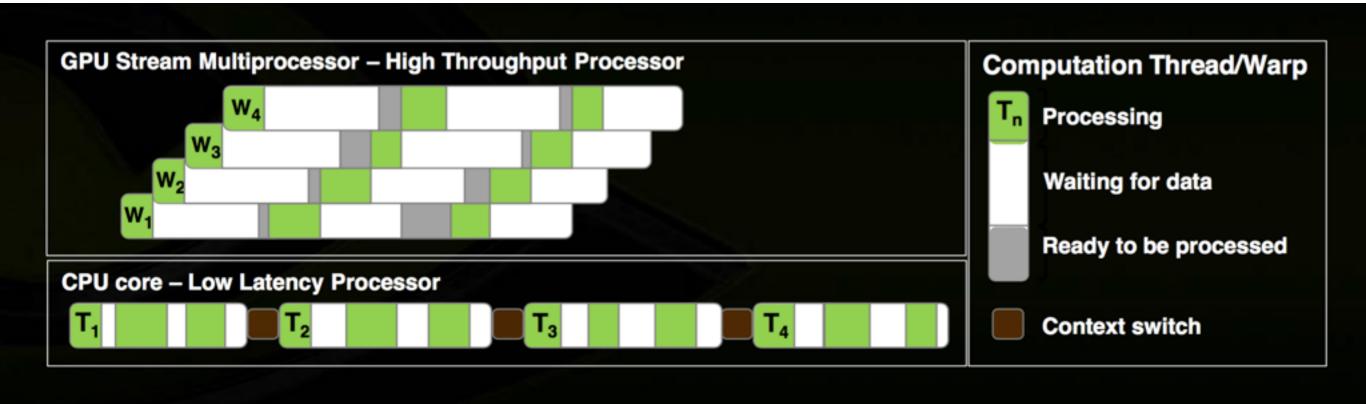

Why?

- The answer: SIMD / vector processing / data parallelism
- Modern CPUs have SIMD instructions (e.g., add vector rather than just add scalar); linear algebra libraries use these effectively
- CPUs can do a handful/dozens of operations at once
- GPUs can do hundreds/thousands of operations at once

Understanding GPUs

- CPUs try to minimize latency
 - speculative branch prediction
 - caching / prefetching memory
- CPUs do one thing at once but do it fast
- GPUs do lots of things (1000's) at once
 - have higher latency, but use latency hiding

CPUs vs GPUs

CUDA C/C++ BASICS

Mostly by NVIDIA Corporation
With some modifications by C Dyer

What is CUDA?

- CUDA Architecture
 - Expose GPU parallelism for general-purpose computing
 - Retain performance
- CUDA C/C++
 - Based on industry-standard C/C++
 - Small set of extensions to enable heterogeneous programming
 - Straightforward APIs to manage devices, memory etc.

Introduction to CUDA C/C++

- What will you learn in this session?
 - Start from "Hello World!"
 - Write and launch CUDA C/C++ kernels
 - Manage GPU memory
 - Manage communication and synchronization

CONCEPTS

HELLO WORLD!

Heterogeneous Computing

- Terminology:
 - Host The CPU and its memory (host memory)
 - Device The GPU and its memory (device memory)

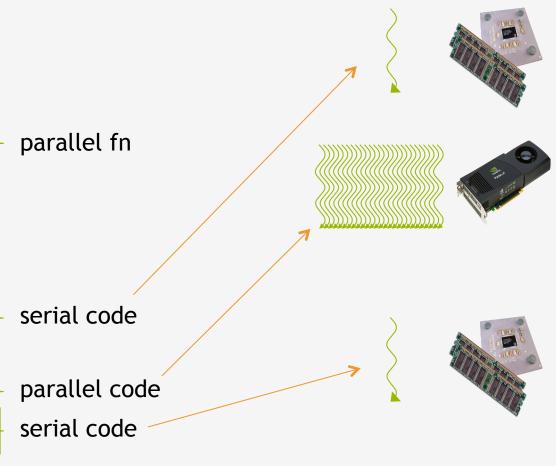

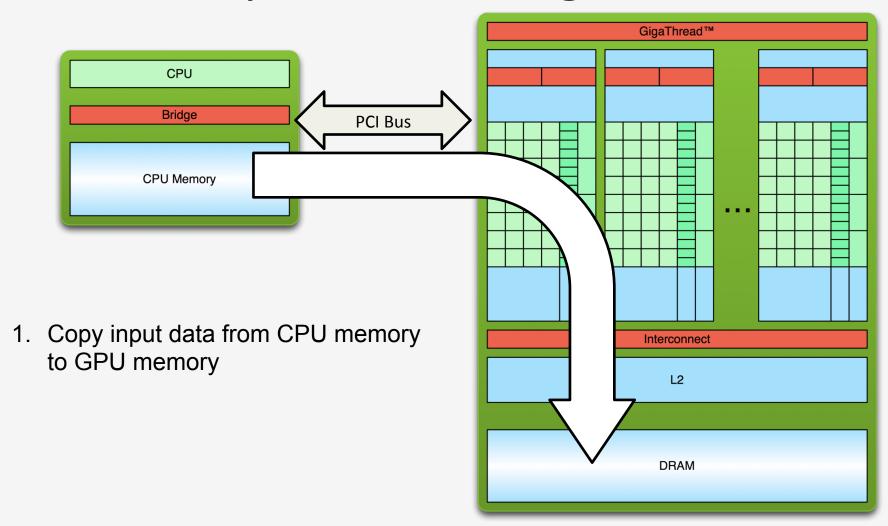

Device

Heterogeneous Computing

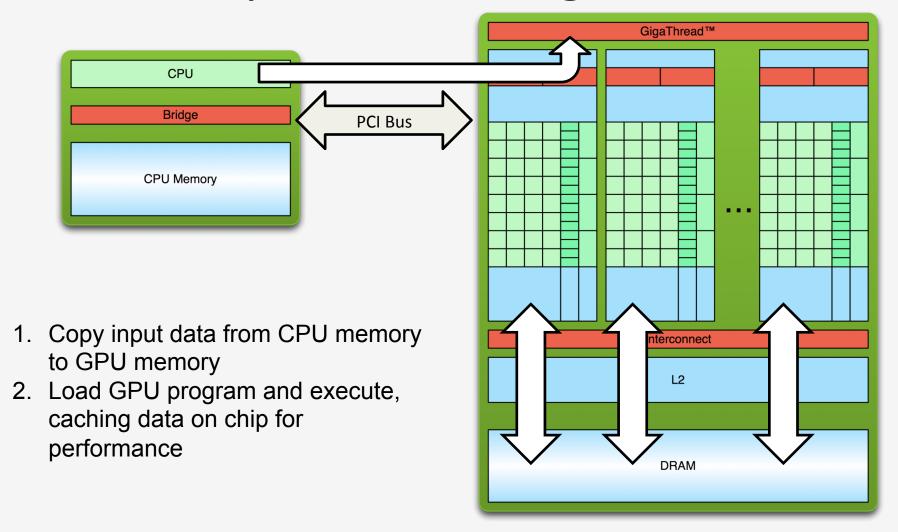

```
using namespace std;
#define N 1024
#define RADIUS 3
#define BLOCK_SIZE 16
__global__ void stencil_1d(int *in, int *out) {
    __shared__ int temp[BLOCK_SIZE + 2 * RADIUS];
        int gindex = threadIdx.x + blockIdx.x * blockDim.x;
int lindex = threadIdx.x + RADIUS;
                temp[lindex - RADIUS] = in[gindex - RADIUS];
                 temp[lindex + BLOCK_SIZE] = in[gindex + BLOCK_SIZE];
        // Synchronize (ensure all the data is available)
         __syncthreads();
        // Apply the stencil
         for (int offset = -RADIUS ; offset <= RADIUS ; offset++)
                result += temp[lindex + offset];
         out[gindex] = result;
void fill ints(int *x, int n) {
        fill_n(x, n, 1);
int main(void) {
                            // host copies of a, b, c
        int *d_in, *d_out;
                               // device copies of a, b, c
        int size = (N + 2*RADIUS) * sizeof(int);
        // Alloc space for host copies and setup values
        in = (int *)malloc(size); fill ints(in, N + 2*RADIUS);
        out = (int *)malloc(size); fill_ints(out, N + 2*RADIUS);
         // Alloc space for device copies
         cudaMalloc((void **)&d_in, size);
        cudaMalloc((void **)&d_out, size);
        // Copy to device cudaMemcpy(d_in, in, size, cudaMemcpyHostToDevice);
         cudaMemcpy(d_out, out, size, cudaMemcpyHostToDevice);
         // Launch stencil 1d/) kernel on GPLI
stencil_1d<<<N/BLOCK_SIZE,BLOCK_SIZE>>>(d_in + RADIUS,
d_out + RADIUS);
         // Copy result back to host
        cudaMemcpy(out, d_out, size, cudaMemcpyDeviceToHost);
         free(in); free(out);
         cudaFree(d_in); cudaFree(d_out);
         return 0:
```

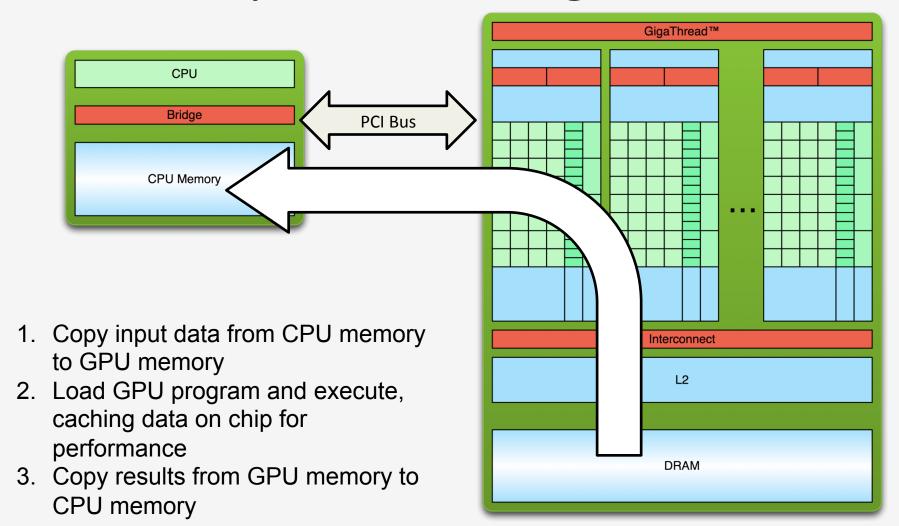

Simple Processing Flow

Simple Processing Flow

Simple Processing Flow

Hello World!

```
int main(void) {
    printf("Hello World!\n");
    return 0;
}
```

- Standard C that runs on the host
- NVIDIA compiler (nvcc) splits code into HOST and DEVICE code and compiles. NVCC can compile programs with no device code

Output:

```
$ nvcc
hello_world.
cu
$ a.out
Hello World!
$
```

```
__global__ void mykernel(void) {
  int main(void) {
    mykernel<<<1,1>>>();
    printf("Hello World!\n");
    return 0;
}
```

Two new syntactic elements...

```
__global___ void mykernel(void) {
}
```

- CUDA C/C++ keyword __global__ indicates a function that:
 - Runs on the device
 - Is called from host code
- nvcc separates source code into host and device components
 - Device functions (e.g. mykernel()) processed by NVIDIA compiler
 - Host functions (e.g. main()) processed by standard host compiler
 - gcc, cl.exe

```
mykernel<<<1,1>>>();
```

- Triple angle brackets mark a call from host code to device code
 - Also called a "kernel launch"
 - We'll return to the parameters (1,1) in a moment

 That's all that is required to execute a function on the GPU!

```
__global___ void mykernel(void) {
}

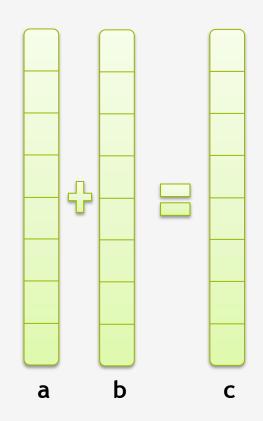

Output:
int main(void) {
    mykernel<<<1,1>>>();
    printf("Hello World!\n");
    hello.cu
    return 0;
}

Hello World!
$
```

 mykernel() does nothing, somewhat anticlimactic!

Parallel Programming in CUDA C/C++

- But wait... GPU computing is about massive parallelism!
- We need a more interesting example...
- We'll start by adding two integers and build up to vector addition

Addition on the Device

A simple kernel to add two integers

```
__global__ void add(int *a, int *b, int *c) {
    *c = *a + *b;
}
```

- As before __global__ is a CUDA C/C++ keyword meaning
 - add() will execute on the device
 - add() will be called from the host

Addition on the Device

Note that we use pointers for the variables

```
__global__ void add(int *a, int *b, int *c) {
    *c = *a + *b;
}
```

- add() runs on the device, so a, b and c must point to device memory
- We need to allocate memory on the GPU

Memory Management

- Host and device memory are separate entities
 - Device pointers point to GPU memory
 May be passed to/from host code
 May not be dereferenced in host code

Host pointers point to CPU memory
 May be passed to/from device code
 May not be dereferenced in device code

- Simple CUDA API for handling device memory
 - cudaMalloc(), cudaFree(), cudaMemcpy()
 - Similar to the C equivalents malloc(), free(), memcpy()

Addition on the Device: add()

Returning to our add() kernel

```
__global__ void add(int *a, int *b, int *c) {
    *c = *a + *b;
}
```

• Let's take a look at main()...

Addition on the Device: main()

```
int main(void) {
                          // host copies of a, b, c
       int a, b, c;
       int *d a, *d b, *d c;  // device copies of a, b, c
       int size = sizeof(int);
       // Allocate space for device copies of a, b, c
       cudaMalloc((void **)&d a, size);
       cudaMalloc((void **)&d b, size);
       cudaMalloc((void **)&d c, size);
      // Setup input values
      a = 2;
      b = 7;
```

Addition on the Device: main()

```
// Copy inputs to device
cudaMemcpy(d a, &a, size, cudaMemcpyHostToDevice);
cudaMemcpy(d b, &b, size, cudaMemcpyHostToDevice);
// Launch add() kernel on GPU
add<<<1,1>>>(d a, d b, d c);
// Copy result back to host
cudaMemcpy(&c, d c, size, cudaMemcpyDeviceToHost);
// Cleanup
cudaFree(d a); cudaFree(d b); cudaFree(d c);
return 0;
```

RUNNING IN PARALLEL

Moving to Parallel

- GPU computing is about massive parallelism
 - So how do we run code in parallel on the device?

```
add<<< 1, 1 >>>();

add<<< N, 1 >>>();
```

 Instead of executing add() once, execute N times in parallel

Vector Addition on the Device

- With add() running in parallel we can do vector addition
- Terminology: each parallel invocation of add() is referred to as a block
 - The set of blocks is referred to as a grid
 - Each invocation can refer to its block index using blockidx.x

```
__global__ void add(int *a, int *b, int *c) {
    c[blockIdx.x] = a[blockIdx.x] + b[blockIdx.x];
}
```

By using blockIdx.x to index into the array, each block handles
a different index

Vector Addition on the Device

```
__global__ void add(int *a, int *b, int *c) {
    c[blockIdx.x] = a[blockIdx.x] + b[blockIdx.x];
}
```

On the device, each block can execute in parallel:

Vector Addition on the Device: add()

Returning to our parallelized add() kernel

```
__global__ void add(int *a, int *b, int *c) {
    c[blockIdx.x] = a[blockIdx.x] + b[blockIdx.x];
}
```

• Let's take a look at main()...

Vector Addition on the Device: main()

```
#define N 512
int main(void) {
   int *a *b *c
                                 // host copies of a, b, c
   int *d a, *d b, *d c; // device copies of a, b, c
   int size = N * sizeof(int);
   // Alloc space for device copies of a, b, c
   cudaMalloc((void **)&d a, size);
   cudaMalloc((void **)&d b, size);
   cudaMalloc((void **)&d c, size);
   // Alloc space for host copies of a, b, c and setup input values
   a = (int *)malloc(size); random ints(a, N);
   b = (int *)malloc(size); random ints(b, N);
   c = (int *)malloc(size);
```

Vector Addition on the Device: main()

```
// Copy inputs to device
cudaMemcpy(d a, a, size, cudaMemcpyHostToDevice);
cudaMemcpy(d b, b, size, cudaMemcpyHostToDevice);
// Launch add() kernel on GPU with N blocks
add <<< N, 1>>> (d a, d b, d c);
// Copy result back to host
cudaMemcpy(c, d c, size, cudaMemcpyDeviceToHost);
// Cleanup
free(a); free(b); free(c);
cudaFree(d a); cudaFree(d b); cudaFree(d c);
return 0;
```

Review (1 of 2)

- Difference between host and device
 - Host CPU
 - Device GPU
- Using __global__ to declare a function as device code
 - Executes on the device
 - Called from the host
- Passing parameters from host code to a device function

Review (2 of 2)

- Basic device memory management
 - cudaMalloc()
 - cudaMemcpy()
 - cudaFree()

- Launching parallel kernels
 - Launch N copies of add() with add<<< N,1>>> (...);
 - Use blockIdx.x to access block index

CONCEPTS Heterogeneous Computing Blocks **Threads** Indexing Shared memory __syncthreads() Asynchronous operation Handling errors

INTRODUCING THREADS

Managing devices

CUDA Threads

Terminology: a block can be split into parallel threads

 Let's change add() to use parallel threads instead of parallel blocks

```
__global__ void add(int *a, int *b, int *c) {
    c[threadIdx.x] = a[threadIdx.x] + b[threadIdx.x];
}
```

- We use threadIdx.x instead of blockIdx.x
- Need to make one change in main()...

Vector Addition Using Threads: main()

```
#define N 512
int main(void) {
   int *a, *b, *c;
                                         // host copies of a, b, c
    int *d a, *d b, *d c;  // device copies of a, b, c
    int size = N * sizeof(int);
    // Alloc space for device copies of a, b, c
    cudaMalloc((void **)&d a, size);
    cudaMalloc((void **)&d b, size);
    cudaMalloc((void **)&d c, size);
    // Alloc space for host copies of a, b, c and setup input values
   a = (int *)malloc(size); random ints(a, N);
   b = (int *)malloc(size); random ints(b, N);
   c = (int *)malloc(size);
```

Vector Addition Using Threads: main()

```
// Copy inputs to device
cudaMemcpy(d a, a, size, cudaMemcpyHostToDevice);
cudaMemcpy(d b, b, size, cudaMemcpyHostToDevice);
// Launch add() kernel on GPU with N threads
add < < 1, N >>> (d a, d b, d c);
// Copy result back to host
cudaMemcpy(c, d c, size, cudaMemcpyDeviceToHost);
// Cleanup
free(a); free(b); free(c);
cudaFree(d a); cudaFree(d b); cudaFree(d c);
return 0;
```

CONCEPTS Heterogeneous Computing Blocks **Threads** Indexing Shared memory __syncthreads() Asynchronous operation Handling errors Managing devices

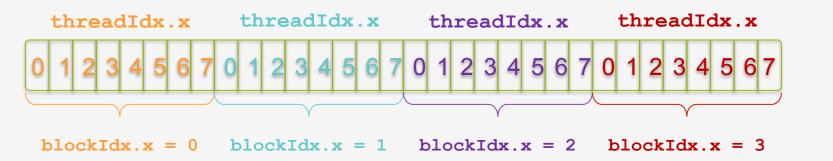

COMBINING THREADS AND BLOCKS

Combining Blocks and Threads

- We've seen parallel vector addition using:
 - Many blocks with one thread each
 - One block with many threads
- Let's adapt vector addition to use both blocks and threads
- Why? We'll come to that...
- First let's discuss data indexing...

Indexing Arrays with Blocks and Threads

- No longer as simple as using blockIdx.x and threadIdx.x
 - Consider indexing an array with one element per thread (8 threads/block)

 With M threads/block a unique index for each thread is given by:

```
int index = threadIdx.x + blockIdx.x * M;
```

Indexing Arrays: Example

 Which thread will operate on the red element?

```
int index = threadIdx.x + blockIdx.x * M;
= 5 + 2 * 8;
= 21;
```

Vector Addition with Blocks and Threads

• Use the built-in variable ыlockDim.x for threads per block

```
int index = threadIdx.x + blockIdx.x * blockDim.x;
```

 Combined version of add() to use parallel threads and parallel blocks

```
__global__ void add(int *a, int *b, int *c) {
    int index = threadIdx.x + blockIdx.x * blockDim.x;
    c[index] = a[index] + b[index];
}
```

What changes need to be made in main()?

Addition with Blocks and Threads: main()

```
#define N (2048*2048)
#define THREADS PER BLOCK 512
int main(void) {
   int *a, *b, *c;
                                         // host copies of a, b, c
    int *d a, *d b, *d c;  // device copies of a, b, c
    int size = N * sizeof(int);
    // Alloc space for device copies of a, b, c
    cudaMalloc((void **)&d a, size);
    cudaMalloc((void **)&d b, size);
    cudaMalloc((void **)&d c, size);
    // Alloc space for host copies of a, b, c and setup input values
   a = (int *)malloc(size); random ints(a, N);
   b = (int *)malloc(size); random ints(b, N);
   c = (int *)malloc(size);
```

Addition with Blocks and Threads: main()

```
// Copy inputs to device
cudaMemcpy(d a, a, size, cudaMemcpyHostToDevice);
cudaMemcpy(d b, b, size, cudaMemcpyHostToDevice);
// Launch add() kernel on GPU
add<<<\\/THREADS_PER_BLOCK_THREADS_PER_BLOCK>>> (d_a, d_b, d_c);
// Copy result back to host
cudaMemcpy(c, d_c, size, cudaMemcpyDeviceToHost);
// Cleanup
free(a); free(b); free(c);
cudaFree(d a); cudaFree(d b); cudaFree(d c);
return 0;
```

Handling Arbitrary Vector Sizes

- Typical problems are not friendly multiples of blockDim.x
- Avoid accessing beyond the end of the arrays:

```
__global___ void add(int *a, int *b, int *c, int n) {
    int index = threadIdx.x + blockIdx.x * blockDim.x;
    if (index < n)
        c[index] = a[index] + b[index];
}</pre>
```

Update the kernel launch:

```
add <<<(N + M-1) / M, M>>>(d_a, d_b, d_c, N);
```

Branching in CUDA Kernels

- Best performance when branches are minimized or small
- Using ternary operator can avoid some branches

Why Bother with Threads?

- Threads seem unnecessary
 - They add a level of complexity
 - What do we gain?
- Unlike parallel blocks, threads have mechanisms to:
 - Communicate
 - Synchronize
- To look closer, we need a new example...

Review

- Launching parallel kernels
 - Launch n copies of add() with add<<<n/м,м>>>(...);
 - Use blockIdx.x to access block index
 - Use threadIdx.x to access thread index within block

Allocate elements to threads:

```
int index = threadIdx.x + blockIdx.x * blockDim.x;
```

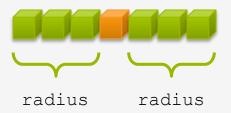

CONCEPTS Heterogeneous Computing Blocks **Threads** Indexing Shared memory __syncthreads() Asynchronous operation Handling errors Managing devices

COOPERATING THREADS

1D Stencil

- Consider applying a 1D stencil to a 1D array of elements
 - Each output element is the sum of input elements within a radius

 If radius is 3, then each output element is the sum of 7 input elements:

Implementing Within a Block

- Each thread processes one output element
 - blockDim.x elements per block

- Input elements are read several times
 - With radius 3, each input element is read seven times

Sharing Data Between Threads

 Terminology: within a block, threads share data via shared memory

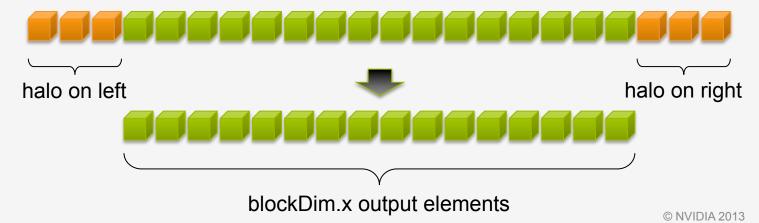

Extremely fast on-chip memory, user-managed

Declare using __shared__, allocated per block

Data is not visible to threads in other blocks

Implementing With Shared Memory

- Cache data in shared memory
 - Read (blockDim.x + 2 * radius) input elements from global memory to shared memory
 - Compute blockDim.x output elements
 - Write blockDim.x output elements to global memory
 - Each block needs a halo of radius elements at each boundary

Stencil Kernel

```
_global__ void stencil_ld(int *in, int *out) {
    _shared__ int temp[BLOCK_SIZE + 2 * RADIUS];
    int gindex = threadIdx.x + blockIdx.x * blockDim.x;
    int lindex = threadIdx.x + RADIUS;

// Read input elements into shared memory
temp[lindex] = in[gindex];
if (threadIdx.x < RADIUS) {
    temp[lindex - RADIUS] = in[gindex - RADIUS];
    temp[lindex + BLOCK_SIZE] =
        in[gindex + BLOCK_SIZE];
}</pre>
```

Stencil Kernel

```
// Apply the stencil
int result = 0;
for (int offset = -RADIUS ; offset <= RADIUS ; offset++)
  result += temp[lindex + offset];

// Store the result
out[gindex] = result;</pre>
```

Data Race!

- The stencil example will not work...
- Suppose thread 15 reads the halo before thread 0 has fetched it...

__syncthreads()

• void syncthreads();

- Synchronizes all threads within a block
 - Used to prevent RAW / WAR / WAW hazards

- All threads must reach the barrier
 - In conditional code, the condition must be uniform across the block

Stencil Kernel

```
global void stencil 1d(int *in, int *out) {
    shared int temp[BLOCK SIZE + 2 * RADIUS];
  int gindex = threadIdx.x + blockIdx.x * blockDim.x;
  int lindex = threadIdx.x + radius;
  // Read input elements into shared memory
  temp[lindex] = in[gindex];
  if (threadIdx.x < RADIUS) {</pre>
      temp[lindex - RADIUS] = in[gindex - RADIUS];
      temp[lindex + BLOCK SIZE] = in[gindex + BLOCK SIZE];
  // Synchronize (ensure all the data is available)
    syncthreads();
```

Stencil Kernel

```
// Apply the stencil
int result = 0;
for (int offset = -RADIUS ; offset <= RADIUS ; offset++)
    result += temp[lindex + offset];

// Store the result
out[gindex] = result;</pre>
```

Review (1 of 2)

- Launching parallel threads
 - Launch N blocks with M threads per block with kernel<<<N,M>>> (...);
 - Use blockIdx.x to access block index within grid
 - Use threadIdx.x to access thread index within block

Allocate elements to threads:

```
int index = threadIdx.x + blockIdx.x * blockDim.x
```

Review (2 of 2)

- Use <u>_shared</u> to declare a variable/array in shared memory
 - Data is shared between threads in a block
 - Not visible to threads in other blocks

- Use syncthreads() as a barrier
 - Use to prevent data hazards

Heterogeneous Computing Blocks Threads Indexing Shared memory __syncthreads()

MANAGING THE DEVICE

Asynchronous operation

Handling errors

Managing devices

Coordinating Host & Device

- Kernel launches are asynchronous
 - Control returns to the CPU immediately

CPU needs to synchronize before consuming the results

```
cudaMemcpy()

Blocks the CPU until the copy is complete
Copy begins when all preceding CUDA calls have
completed

cudaMemcpyAsync()

Asynchronous, does not block the CPU

cudaDeviceSynchro

Blocks the CPU until all preceding CUDA calls have
completed
```

Reporting Errors

- All CUDA API calls return an error code (cudaError_t)
 - Error in the API call itselfOR
 - Error in an earlier asynchronous operation (e.g. kernel)
- Get the error code for the last error:

```
cudaError t cudaGetLastError(void)
```

Get a string to describe the error:

```
char *cudaGetErrorString(cudaError_t)
```

```
printf("%s\n", cudaGetErrorString(cudaGetLastError()));
```

Device Management

Application can query and select GPUs

```
cudaGetDeviceCount(int *count)
cudaSetDevice(int device)
cudaGetDevice(int *device)
cudaGetDeviceProperties(cudaDeviceProp *prop, int device)
```

- Multiple threads can share a device
- A single thread can manage multiple devices

```
cudaSetDevice(i) to select current device
cudaMemcpy(...) for peer-to-peer copies †
```

Introduction to CUDA C/C++

- What have we learned?
 - Write and launch CUDA C/C++ kernels
 - global__, blockIdx.x, threadIdx.x, <<<>>>
 - Manage GPU memory
 - cudaMalloc(), cudaMemcpy(), cudaFree()
 - Manage communication and synchronization
 - __shared__, __syncthreads()
 - cudaMemcpy() VS cudaMemcpyAsync(),
 cudaDeviceSynchronize()

Side-by-side Algorithms

Compute: $\mathbf{y} = \alpha \mathbf{x} + \mathbf{y}$ "SAXPY"

Side-by-side Algorithms

Compute: $\mathbf{y} = \alpha \mathbf{x} + \mathbf{y}$ "SAXPY"

```
void saxpy_serial(int n, float a, float *x, float *y)
   for (int i = 0; i < n; ++i)
       y[i] = a*x[i] + y[i];
                                               Standard C Code
// Invoke serial SAXPY kernel
saxpy_serial(n, 2.0, x, y);
__global__ void saxpy_parallel(int n, float a, float *x, float *y)
   int i = blockIdx.x*blockDim.x + threadIdx.x;
                                                 Parallel C Code
   if (i < n) y[i] = a*x[i] + y[i];
// Invoke parallel SAXPY kernel with 256 threads/block
int nblocks = (n + 255) / 256;
saxpy_parallel <<< nblocks, 256 >>> (n, 2.0, x, y);
```

CUDA Libraries

- CUBLAS fast BLAS implementation with standard BLAS API
- CUFFT FFT library
- CURAND generate lots of pseudorandom numbers
- CUSPARSE sparse linear algebra
- CUDNN primitives for Neural Networks / Deep Learning (convolutions, softmaxes, etc)

Advice I

- Always do some linear algebra
 - Not just for MATLAB/Python for all modern hardware, not just GPUs
 - Shorter code, faster execution!
- GPU programming is difficult (CPUs are designed to shield you from hardware quirks, but GPUs expose them to you), and newer GPU architectures change optimal usage patterns
 - GPU memory and PCI busses are slow so things quickly become memory bound
 - Use customized, high-level libraries when you can
 - Only write in CUDA what you absolutely have to
 - Unfortunately, GPUs are new: you might find what you need, you might not!
- GPUs shine when there is lots of computation per unit of memory (matrix-matrix multiply!)

Advice II

- Memory allocation and copying is horrendously expensive
 - Use big blocks, handle it yourself, stay on the GPU as much as possible
- GPUs work well by latency hiding
 - Do lots of stuff in parallel
 - cudaStreams are one high level mechanism for doing this
- Asynchronous calls help improve scheduling- pay attention to whether your library is behaving synchronously or asynchronously

Questions
